1 Introduction

This document is targeted at developers and describes the overall design of the CML simulator, it is not a detailed description of each component. This kind of documentation is done in Javadoc and can be generated automatically from the code. It is assumed that common design patterns are known like ??.

1.1 Problem Domain

The goal of the interpreter is to enable simulation/animation of a given CML ?? model and be able to visualize this in the Eclipse IDE Debugger. CML has a UTP semantics defined in ?? which dictates how the interpretation progresses. Therefore, the overall goal of the CML interpreter is to adhere to the semantic rules defined in those documents and to somehow visualize this in the Eclipse Debugger.

In order to get a high level understanding of how CML is interpreted without knowing all the details of the semantics and the implementation of it. A short illustration of how the interpreter represents and progresses a CML model is given below.

In listing 1 a CML model consisting of three CML processes is given. It has a R (Reader) process which reads a value from the input channel and writes it on the output channel. The W (Writer) process writes the value 1 to the input channel and finishes. The S (System) process is a parallel composition of these two processes where they must synchronize all events on the input channel.

```

50 channels
51 inp : int
52 out : int
53
54 process W =
55 begin
56   @ inp!1 -> Skip
57 end
58
59 process R =
60 begin
61   @ inp?x -> out!x -> Skip
62 end
63
64 process S = W [|{inp}|] R

```

Listing 1: Coordinating a reader and writer process

Write about the example in the same manner as D32.2 description

The interpretation of a CML model is done through a series of steps/transitions starting from a given entry point. In figure ?? which shows the first step, we assume that the System process is given as a starting point, it is represented as a circle along with its current position in the model. Each step of the interpretation can be split up into two phases, the inspection phase and the execution phase.

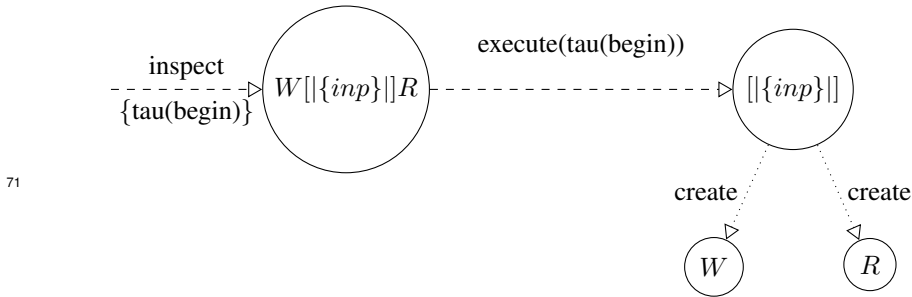

Figure 1: Initial step of Listing 1 with process S as entry point.

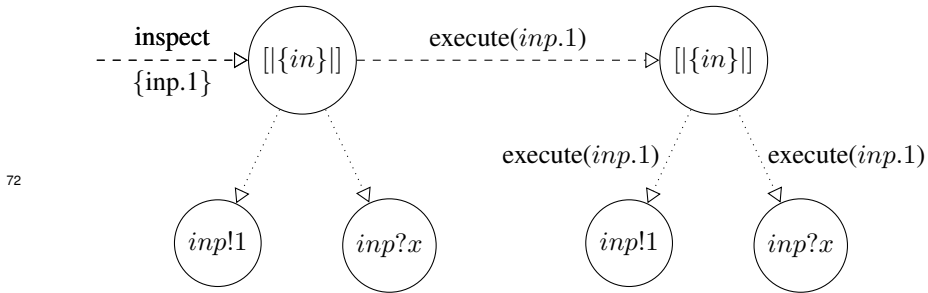

Figure 2: Second step of Listing 1 with S as entry point.

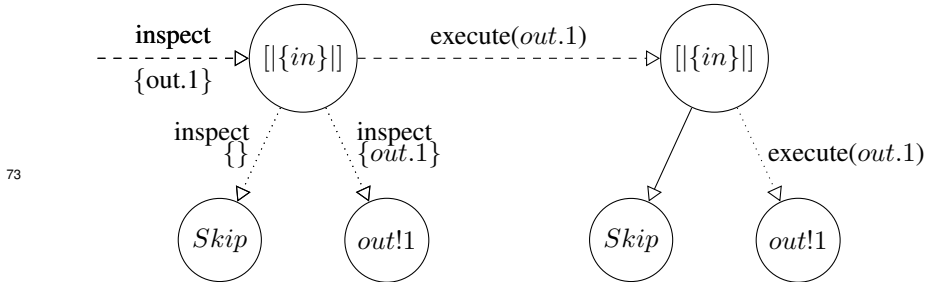

Figure 3: Third step of Listing 1 with S as entry point

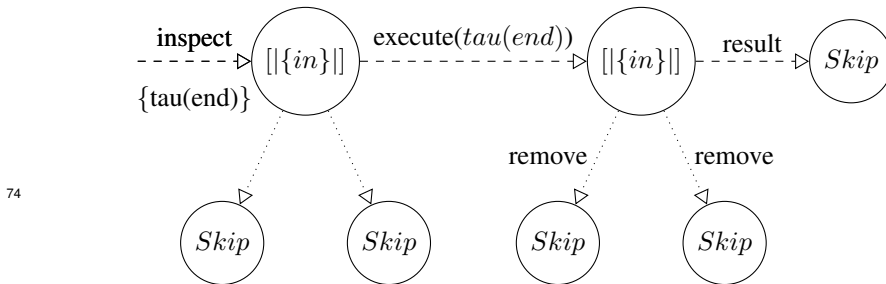

Figure 4: Final step of Listing 1 where the parallel composition collapses unto a Skip process

1.2 Definitions

CML Compass Modelling Language

UTP Unified Theory of Programming, a semantic framework.

Simulation Simulation is when the interpreter runs without any form of user interaction other than starting and stopping.

Animation Animation is when the user are involved in taking the decisions when interpreting the CML model

2 Software Layers

This section describes the layers of the CML interpreter. As depicted in figure 5 two highlevel layers exists.

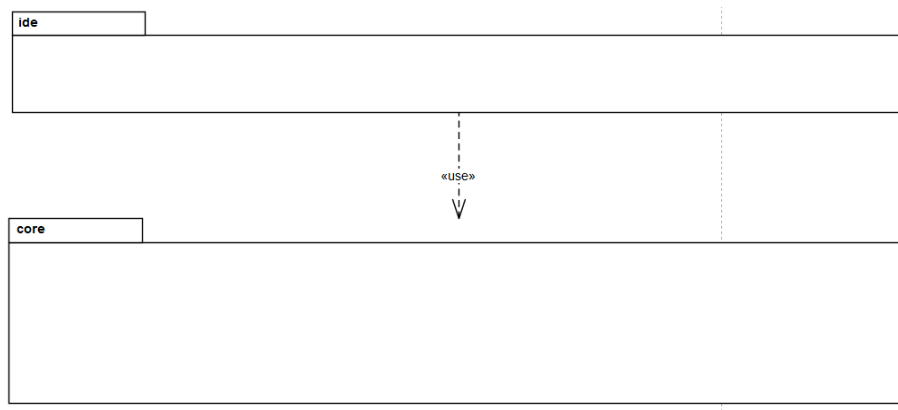

Figure 5: The layers of the CML Interpreter

Core layer Has the responsibility of interpreting a CML model as described in the operational semantics that are defined in [?] and is located in the java package named *eu.compassresearch.core.interpreter*

IDE layer Has the responsibility of visualizing the outputs of a running interpretation a CML model in the Eclipse Debugger. It is located in the *eu.compassresearch.ide.cml.interpreter_plugin* package.

Each of these components will be described in further detail in the following sections.

2.1 The Core Layer

The design philosophy of the top-level structure is to encapsulate all the classes and interfaces that makes up the implementation of the core functionality and only expose those that are needed to utilize the interpreter. This provides a clean separation between the implementation and interface and makes it clear for both the users, which

98 not necessarily wants to know about the implementation details, and developers which
99 parts they need to work with.

100 The following packages defines the top level structure of the core:

101 **eu.compassresearch.core.interpreter.api** This package and sub-packages contains all
102 the public classes and interfaces that defines the API of the interpreter. This
103 package includes the main interpreter interface **CmlInterpreter** along with ad-
104 ditional interfaces. The api sub-packages groups the rest of the API classes and
105 interfaces according to the responsibility they have.

106 **eu.compassresearch.core.interpreter.api.behaviour** This package contains all the com-
107 ponents that define any CML behavior. A CML behaviour is either an observable
108 event like a channel synchronization or a internal event like a change of state.
109 The main interface is **CmlBehaviour**.

110 **eu.compassresearch.core.interpreter.api.events** This package contains all the public
111 components that enable users of the interpreter to subscribe to multiple on events
112 (this it not CML channel events) from both **CmlInterpreter** and **CmlBehaviour**
113 instances.

114 **eu.compassresearch.core.interpreter.api.transitions** This package contains all the
115 possible types of transitions that a **CmlBehaviour** instance can make. This will
116 be explained in more detail in section 3.1.2.

117 **eu.compassresearch.core.interpreter.api.values** This package contains all the values
118 used in the CML interpreter. Values are used to represent the the result of an
119 expression or the current state of a variable.

120 **eu.compassresearch.core.interpreter.debug** TBD

121 **eu.compassresearch.core.interpreter.utility** The utility packages contains components
122 that generally reusable classes and interfaces.

123 **eu.compassresearch.core.interpreter.utility.events** This package contains components
124 helps to implement the Observer pattern.

125 **eu.compassresearch.core.interpreter.utility.messaging** This package contains gen-
126 eral components to pass message along a stream.

127 **eu.compassresearch.core.interpreter** This package contains all the internal classes
128 and interfaces that defines the core functionality of the interpreter. There is
129 one important public class in the package, namely the **VanillaInterpreteFactory**
130 faactory class, that any user of the interpreter must invoke to use the interpreter.
131 This can creates **CmlInterpreter** instances.

132 The **eu.compassresearch.core.interpreter** package are split into several folders, each
133 representing a different logical component. The following folders are present

134 **behavior** This folder contains all the internal classes and interfaces that implements
135 the CmlBehaviors. The Cml behaviors will be described in more detail in in
136 section 3.1.1, but they are basically implemented by CML AST visitor classes.

137 **factories** This folder contains all the factories in the package, both the public **Vanil-**
138 **laInterpreteFactory** that creates the interpreter and package internal ones.

139 **utility**

140 ...

141 2.2 The IDE Layer

142 The IDE part is integrating the interpreter into Eclipse, enabling CML models to be
 143 debugged/simulated/animated through the Eclipse interface. In Figure 6 a deployment
 144 diagram of the debugging structure is shown.

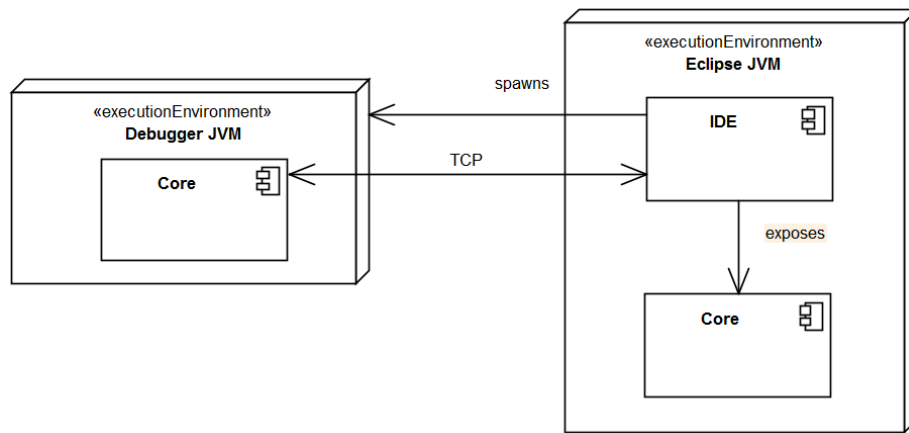

Figure 6: Deployment diagram of the debugger

145 An Eclipse debugging session involves two JVMs, the one that the Eclipse platform
 146 is executing in and one where only the Core executes in. All communication between
 147 them is done via a TCP connection.

148 Before explaining the steps involved in a debugging session, there are two important
 149 classes worth mentioning:

- 150 • **CmlInterpreterController**: This is responsible for controlling the CmlInter-
 151 preter execution in the debugger JVM. All communications to and from the in-
 152 terpreter handled in this class.
- 153 • **CmlDebugTarget**: This class is part of the Eclipse debugging model. It has the
 154 responsibility of representing a running interpreter on the Eclipse JVM side. All
 155 communications to and from the Eclipse debugger are handled in this class.

156 A debugging session has the following steps:

- 157 1. The user launches a debug session
- 158 2. On the Eclipse JVM a **CmlDebugTarget** instance is created, which listens for
 159 an incoming TCP connection.
- 160 3. A Debugger JVM is spawned and a **CmlInterpreterController** instance is cre-
 161 ated.
- 162 4. The **CmlInterpreterController** tries to connect to the created connection.
- 163 5. When the connection is established, the **CmlInterpreterController** instance
 164 will send a **STARTING** status message along with additional details

- 165 6. The **CmlDebugTarget** updates the GUI accordingly.
- 166 7. When the interpreter is running, status messages will be sent from **CmlInter-**
 167 **preterController** and commands and request messages are sent from **CmlDe-**
 168 **bugTarget**
- 169 8. This continues until **CmlInterpreterController** sends the STOPPED message
- 170 TBD...

171 3 Layer design and Implementation

172 This section describes the static and dynamic structure of the components involved in
 173 simulating/animating a CML model.

174 3.1 Core Layer

175 3.1.1 Static Model

176 The top level interface of the interpreter is depicted in figure 7, followed by a short
 description of each the depicted components.

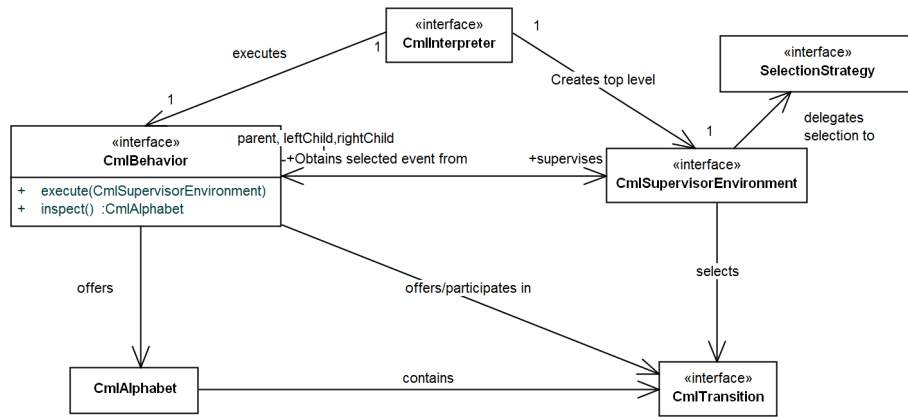

Figure 7: The high level classes and interfaces of the interpreter core component

177

178 **CmlInterpreter** The main interface exposed by the interpreter component. This inter-
 179 face has the overall responsibility of interpreting. It exposes methods to execute,
 180 listen on interpreter events and get the current state of the interpreter. It is imple-
 181 mented by the **VanillaCmlInterpreter** class.

182 **CmlBehaviour** Interface that represents a behaviour specified by either a CML pro-
 183 cess or action. It exposes two methods: *inspect* which calculates the immediate
 184 set of possible transitions that the current behaviour allows and *execute* which
 185 takes one of the possible transitions determined by the supervisor. A specific

behaviour can for instance be the prefix action “a - ζ P”, where the only possible transition is to interact in the a event. in any

CmlSupervisorEnvironment Interface with the responsibility of acting as the supervisor environment for CML processes and actions. A supervisor environment selects and exposes the next transition/event that should occur to its pupils (All the CmlBehaviors under its supervision). It also resolves possible backtracking issues which may occur in the internal choice operator.

SelectionStrategy This interface has the responsibility of choosing an event from a given CmlAlphabet. This responsibility is delegated by the CmlSupervisorEnvironment interface.

CmlTransition Interface that represents any kind of transition that a CmlBehavior can make. This structure will be described in more detail in section ??.

CmlAlphabet This class is a set of CmlTransitions. It exposes convenient methods for manipulating the set.

To gain a better understanding of figure 7 a few things needs mentioning. First of all any CML model (at least for now) has a top level Process. Because of this, the interpreter need only to interact with the top level CmlBehaviour instance. This explains the one-to-one correspondence between the CmlInterpreter and the CMLBehaviour. However, the behavior of top level CmlBehaviour is determined by the binary tree of CmlBehaviour instances that itself and it's child behaviours defines. So in effect, the CmlInterpreter controls every transition that any CmlBehaviour makes through the top level behaviour.

3.1.2 Transition Model

As described in the previous section a CML model is represented by a binary tree of CmlBehaviour instances and each of these has a set of possible transitions that they can make. A class diagram of all the classes and interfaces that makes up transitions are shown in figure 8, followed by a description of each of the elements.

A transition taken by a CmlBehavior is represented by a CMLTransition. This represent a possible next step in the model which can be either observable or silent (also called a tau transition).

An observable transition represents either that time passes or that a communication/synchronization event takes place on a given channel. All of these transitions are captured in the ObservableTransition interface. A silent transitions is captured by the TauTransition and HiddenTransition class and can respectively marks the occurrence of a an internal transition of a behavior or a hidden channel transition.

CmlTransition Represents any possible transition.

CmlTransitionSet Represents a set of CmlTransition objects.

ObservableTransition This represents any observable transition.

LabelledTransition This represents any transition that results in a observable channel event

TimedTransition This represents a tock event marking the passage of a time unit.

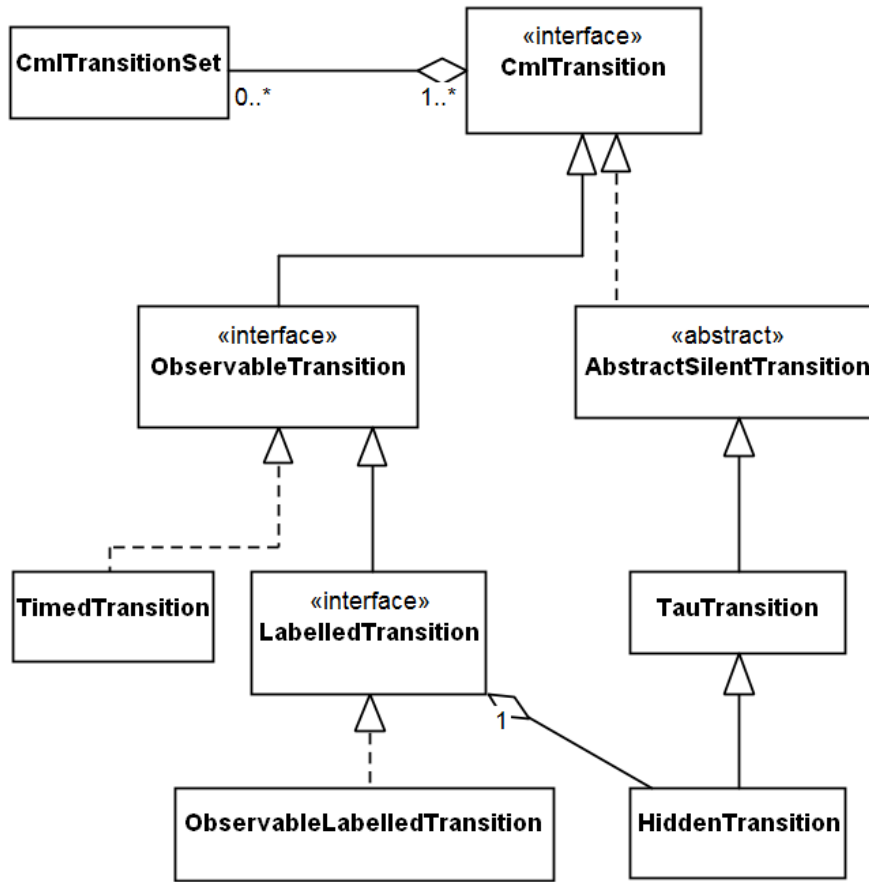

Figure 8: The classes and interfaces that defines transitions/events

227 **ObservableLabelledTransition** This represents the occurrence of a observable chan-
 228 nel event which can be either a communication event or a synchronization event.

229 **TauTransition** This represents any non-observable transitions that can be taken in a
 230 behavior.

231 **HiddenEvent** This represents the occurrence of a hidden channel event in the form of
 232 a tau transition.

233 3.1.3 Action/Process Structure

234 Actions and processes are both represented by the CmlBehaviour interface. A class
 235 diagram of the important classes that implements this interface is shown in figure 9

236
 237 As shown the **ConcreteCmlBehavior** is the implementing class of the CmlBehavior
 238 interface. However, it delegates a large part of its responsibility to other classes. The
 239 actual behavior of a ConcreteCmlBehavior instance is decided by its current instance

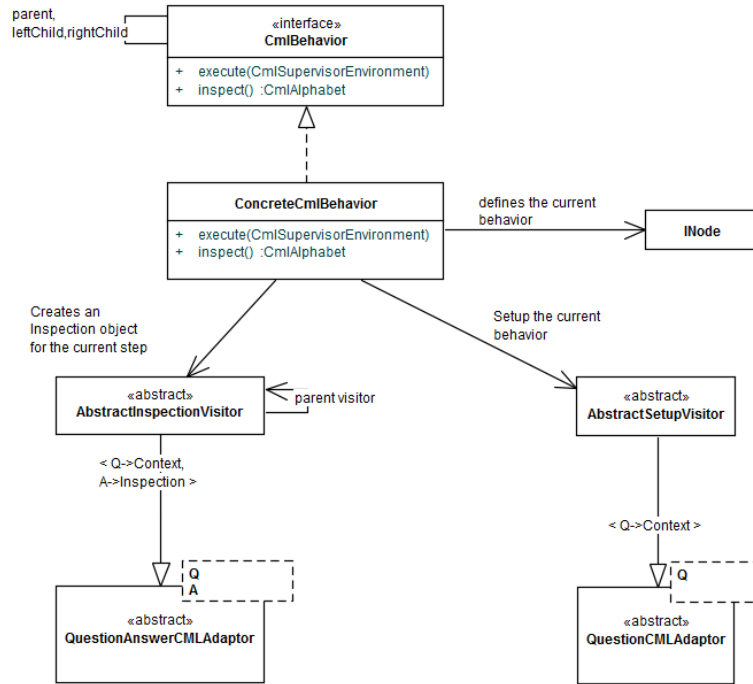

Figure 9: The implementing classes of the CmlBehavior interface

240 of the INode interface, so when a ConcreteCmlBehavior instance is created a INode
 241 instance must be given. The INode interface is implemented by all the CML AST
 242 nodes and can therefore be any CML process or action. The actual implementation
 243 of the behavior of any process/action is delegated to three different kinds of visitors
 244 all extending a generated abstract visitor that have the infrastructure to visit any CML
 245 AST node.

246 The following three visitors are used:

247 **AbstractSetupVisitor** This has the responsibility of performing any required setup
 248 for every behavior. This visitor is invoked whenever a new INode instance is
 249 loaded.

250 **AbstractEvaluationVisitor** This has the responsibility of performing the actual be-
 251 havior and is invoked inside the **execute** method. This involves taking one of the
 252 possible transitions.

253 **AbstractAlphabetVisitor** This has the responsibility of calculating the alphabet of
 254 the current behavior and is invoked in the **inspect** method.

255 In figure 10 a more detailed look at the evaluation visitor structure is given.

256 As depicted the visitors are split into several visitors that handle different parts of the
 257 languages. The sole reason for doing this is to avoid having one large visitor that
 258 handles all the cases. At run-time the visitors are setup in a tree structure where the
 259 top most visitor is a **CmlEvaluationVisitor** instance which then delegates to either a

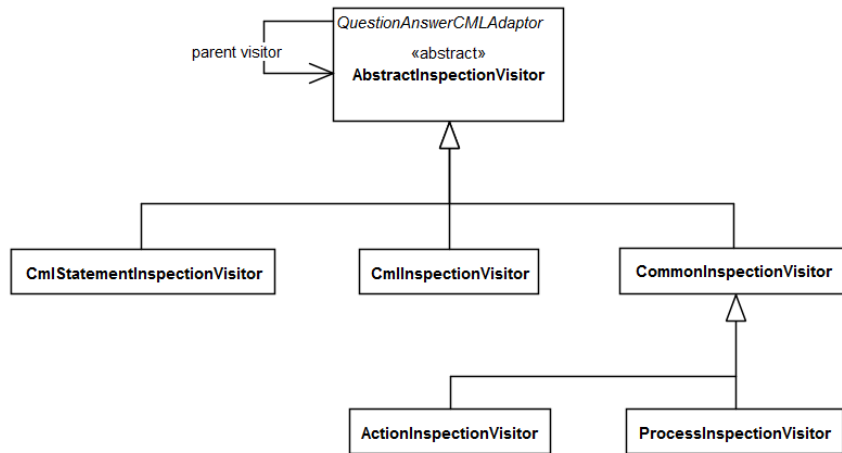

Figure 10: Visitor structure

260 **ActionEvaluationVisitor** and **ProcessEvaluationVisitor** etc.

261 3.1.4 Dynamic Model

262 The previous section described the high-level static structure, this section will describe
 263 the high-level dynamic structure.

264 First of all, the entire CML interpreter runs in a single thread. This is mainly due
 265 to the inherent complexity of concurrent programming. You could argue that since
 266 a large part of COMPASS is about modelling complex concurrent systems, we also
 267 need a concurrent interpretation of the models. However, the semantics is perfectly
 268 implementable in a single thread which makes a multi-threaded interpreter optional.
 269 There are of course benefits to a multi-threaded interpreter such as performance, but
 270 for matters such as the testing and deterministic behaviour a single threaded interpreter
 271 is much easier to handle and comprehend.

272 To start a simulation/animation of a CML model, you first of all need an instance of the
 273 **CmlInterpreter** interface. This is created through the **VanillaInterpreterFactory** by
 274 invoking the **newInterpreter** method with a typechecked AST of the CML model. The
 275 currently returned implementation is the **VanillaCmlInterpreter** class. Once a **Cm-**
 276 **Interpreter** is instantiated the interpretation of the CML model is started by invoking
 277 the **execute** method given a **CmlSupervisorEnvironment**.

278 In figure 11 a high level sequence diagram of the **execute** method on the **VanillaCm-**
 279 **Interpreter** class is depicted.

280 As seen in the figure the model is executed until the top level process is either success-
 281 fully terminated or deadlocked. For each

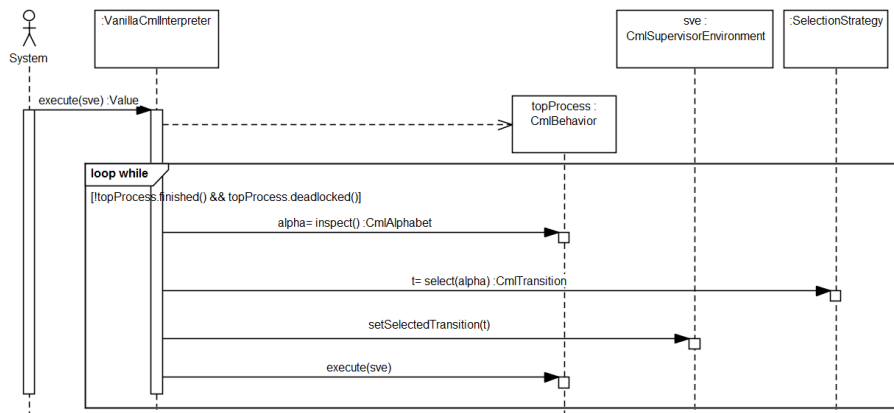

Figure 11: The top level dynamics

282 3.1.5 CmlBehaviors

283 As explained in section ?? the CmlBehavior instances forms a binary tree at run-
 284 time.

285 3.2 The IDE Layer
